A METHOD FOR REALISTIC FLAVOUR EXPECTATIONS?
The question is familiar to all of us: By assessing cone hops or pellets, how do I know what to expect from this hop when used in late hopping in terms of flavour? These Japanese researchers have developed a standardised method that is useful for this type of assessment. For this method, 0.5g of alpha acids per liter were added to distilled water and boiled at 105°C for 5 minutes. Bitter and aroma compounds were analysed and sensory flavour profiling conducted. Though a significant correlation between sensory and analytical data was not achieved, the flavour profiling gave reproducible insights in the flavour properties of the hop varieties studied.¹

DRY HOPPING: MORE OIL = MORE HOPPY?
If I would ask you if you think a higher addition of hop oil equivalent for dry hopping would result in a hoppiest beer, I am sure all of you would be quite confident that this is correct. However US researchers say perhaps not. An unhopped beer was dry hopped with 23 individual Cascade hop lots, and the resultant beer was evaluated with sensory descriptive analysis. The results demonstrated a negligible role of total oil content (mL/100 g) as an indicator of hopiness. In fact, there was no correlation between total oil content and overall hop aroma intensity with this study. The Cascade samples had oil contents ranging from 0.6 up to 2 mL/100g of hops. I am as surprised as you are, but wouldn’t life be boring without occasional results such as these?²

LATER HARVEST DATE = MORE INTENSE DRY HOP AROMA?
Previous studies have shown that harvest date can have a significant impact on the flavour profile of beer depending on hop variety. To further illustrate the effect, this study evaluated the variety Mandarina Bavaria. These German researchers produced dry hopped beers with Mandarina Bavaria hops harvested at different dates within a 4 week period. Although it was shown that some of the known important hop aromatic compounds in dry hopped beers (especially myrcene) changed in concentration when using hops with different harvest dates, with other compounds (especially linalool) the result of sensory data showed that the harvest date of Mandarina Bavaria is not important for final top-fermented beer aroma. It is unclear which aroma components are the key components of Mandarina Bavaria.³
